Pelletizing of stalk material
Self-propelling harvesters
PASSION  
FLEXIBILITY

The Metitron is a compact vehicle with all the merits of an established brand of self-driving forage harvester.

The operator can use the machine in two ways: firstly, field use and secondly, yard use. A continuously variable hydrostatic engine on all four wheels considerably simplifies driving in the field, even on rough terrain. This design concept makes it possible to use the entire range of front attachments such as a maize head for miscanthus, as well as grain and alfalfa via direct cutters. The basic machine manufacturer’s pickup can be used for other materials.

As the trials have been completed under real conditions with the raw material miscanthus, straw, hay and spelt husks, the Metitron is now going into series production.
PASSION HAY AND STRAW

Hay pelletizing directly from the field.

Straw pelletizing directly from the square bale.
PASSION
MISCANTHIS

Miscanthus harvest
Pelletizing
UNIQUE FEATURES

- compact structure with the self-propelling agricultural machine
- automatically controlled material feed through the power regulator of the pelleting press engine
- direct press engine from a diesel motor via the power belt to the pelleting press
- Pellet transport after the pelleting press via a pellet bucket conveyor, the pellets being cooled and transported gently
- no pre-warming from the emissions in the pressed product
- patented material crushing integrated in the direct flow of material
- no conversions or attaching to a tractor is necessary
## PERFORMANCE DATA

| Front heads:     | **Pickup from Claas** for hay, straw, alfalfa, sainfoin, etc.  
|                  | **Corn head from Claas** for miscanthus, sida, etc.  
|                  | **Direct Disc from Claas** for whole plant pelleting |
| Energy consumption: | from 15l/t |
Pelletizing the material can offer various advantages:

**Increasing the bulk density**
By pressing the pellets, the bulk density can be significantly increased compared to the starting material. At around 650 - 700 kg/m³, hay and straw pellets, for example, have a much higher bale density than high-pressure bales of around 100 - 160 kg/m³. As a result, storage and transport expenses are significantly lower and the transport worthiness is enhanced.

**Improving the handling of the material**
By converting the small material (e.g. dust/powder, sawdust) into pellets, dust formation during storage, transport or use is avoided. This prevents contamination with toxic materials and prevents dust explosions with flammable materials.

**Standardization of material size**
By converting the starting material into pellets of a certain size, a uniformity of the size-related properties is achieved. Conveyor systems (screw conveyors, etc.), for example, can then be operated reliably. This also improves dosability.

**Improving transportability**
Material that has to be transported in large quantities, such as firewood or animal feed, can be transported quickly and efficiently in pellet form by blowing it via an air stream, e.g. from a truck into a storage silo.

**Avoiding separation**
If the starting material is a heterogeneous mixture of different substances (e.g. animal feed), pelleting can prevent separation.
PELLETS AS BEDDING

From many years of experience, we know how important the right bedding is for optimal stable management, whether in the horse stables, in the pigpen, in the cowshed or in the poultry house. Therefore, there are no compromises on quality. So, what could be more obvious than processing domestic straw or even your own straw into pellets.

Further advantages are 75% less work in the barn compared to conventional straw, a reduction in disposal as 15 times more absorption power is achieved compared to long-stalk straw, it is 100% degradable, and has a high fertilizer value.

The manufacturing process in the Metitron retains the pellets’ sterility as it is approx. 80°C during the pressing process, making it ideal for veterinary clinics. Straw pellets can also be used in pig farming and can be mixed with the liquid manure for disposal.
PELLETS AS FEED

For feeding purposes, whole plants, such as grains, can also be pelletized using the Metitron mower head. Pellets are used as an all-in-one feed or as a supplement. Advantages of pellet feeding are a lower dust load than with grain, no need to separate the individual feed components and good use opportunities for transponder feeding in groups.
HEATING WITH BIOMASS

Plants are renewable raw materials and can significantly contribute long term to the security of supply in one’s own country. Using one’s own arable land, the regional supply reliability, and the comparably minimal production costs make biomass an extremely economical and pioneering alternative. Straw and miscanthus pellets can be burned in pellet heating systems from 60 kW, used in wood chip heating systems and even mixed in.

Benefits of Biomass Heating:
- environmentally friendly, CO2-neutral combustion
- reduces heating costs
- low production and transport costs
- secures jobs and strengthens the region
- virtually unlimited renewability
- significant contribution to the energy revolution
- outstanding alternative to fossil fuels
